Chapter 6
MOBILE
IP AND TCP

Mobile Computing
Summer 2004

Overview

- Network Protocols / Mobile IP
  - Motivation
  - Data transfer
  - Encapsulation
  - Problems
  - DHCP

- Mobile Transport Layer / TCP
  - Motivation
  - Various TCP mechanisms

Motivation for Mobile IP

- Routing
  - Based on IP destination address, network prefix (e.g. 129.132.13) determines physical subnet
  - Change of physical subnet implies change of IP address to have a topological correct address (standard IP) or needs special entries in the routing tables
- Changing the IP-address?
  - Adjust the host IP address depending on the current location
  - Almost impossible to find a mobile system, DNS updates are too slow
  - TCP connections break
  - Security problems
- Change/Add routing table entries for mobile hosts?
  - Worldwide!
  - Does not scale with the number of mobile hosts and frequent changes in their location

Requirements to Mobile IP (RFC 2002)

- Compatibility
  - Support of the same layer 2 protocols as IP
  - No changes to current end-systems and routers required
  - Mobile end-systems can communicate with fixed systems
- Transparency
  - Mobile end-systems keep their IP address
  - Continuation of communication after interruption of link possible
  - Point of connection to the fixed network can be changed
- Efficiency and scalability
  - Only little additional messages to the mobile system required (connection typically via a low bandwidth radio link)
  - World-wide support of a large number of mobile systems
- Security
  - Authentication of all registration messages
Data transfer to the mobile system

1. Sender sends to the IP address of MN, HA intercepts packet (proxy ARP)
2. HA tunnels packet to COA, here FA, by encapsulation
3. FA forwards the packet to the MN

Data transfer from the mobile system

1. Sender sends to the IP address of the receiver as usual, FA works as default router

Terminology

- **Mobile Node (MN)**
  - system (node) that can change the point of connection to the network without changing its IP address
- **Home Agent (HA)**
  - system in the home network of the MN, typically a router
  - registers the location of the MN, tunnels IP datagrams to the COA
- **Foreign Agent (FA)**
  - system in the current foreign network of the MN, typically a router
  - typically the default router for the MN
- **Care-of Address (COA)**
  - address of the current tunnel end-point for the MN (at FA or MN)
  - actual location of the MN from an IP point of view
  - can be chosen, e.g., via DHCP
- **Correspondent Node (CN)**
Overview

Network integration

- Agent Advertisement
  - HA and FA periodically send advertisement messages into their physical subnets
  - MN listens to these messages and detects, if it is in the home or a foreign network (standard case for home network)
  - MN reads a COA from the FA advertisement messages

- Registration (always limited lifetime!)
  - MN signals COA to the HA via the FA, HA acknowledges via FA to MN
  - these actions have to be secured by authentication

- Advertisement
  - HA advertises the IP address of the MN (as for fixed systems), i.e. standard routing information
  - routers adjust their entries, these are stable for a longer time (HA responsible for a MN over a longer period of time)
  - packets to the MN are sent to the HA,
  - independent of changes in COA/FA

Agent advertisement

Generic Routing Encapsulation

Optimization of packet forwarding

- Triangular Routing
  - sender sends all packets via HA to MN
  - higher latency and network load
- “Solutions”
  - sender learns the current location of MN
  - direct tunneling to this location
  - HA informs a sender about the location of MN
  - big security problems
- Change of FA
  - packets on-the-fly during the change can be lost
  - new FA informs old FA to avoid packet loss, old FA now forwards remaining packets to new FA
  - this information also enables the old FA to release resources for the MN

Change of foreign agent

Data transfer from the mobile system

- Firewall at CN
- TTL
- Multicast
Reverse tunneling (RFC 2344)

1. MN sends to FA
2. FA tunnels packets to HA by encapsulation
3. HA forwards the packet to the receiver (standard case)

Mobile IP with reverse tunneling

- Router accept often only “topologically correct” addresses (firewall!)
  - a packet from the MN encapsulated by the FA is now topologically correct
  - furthermore multicast and TTL problems solved (TTL in the home network correct, but MN is too far away from the receiver)
- Reverse tunneling does not solve
  - problems with firewalls, the reverse tunnel can be abused to circumvent security mechanisms (tunnel hijacking)
  - optimization of data paths, i.e. packets will be forwarded through the tunnel via the HA to a sender (double triangular routing)
- Reverse tunneling is backwards compatible
  - the extensions can be implemented easily and cooperate with current implementations without these extensions

Mobile IP and IPv6

- Mobile IP was developed for IPv4, but IPv6 simplifies the protocols
  - security is integrated and not an add-on, authentication of registration is included
  - COA can be assigned via auto-configuration (DHCPv6 is one candidate), every node has address auto-configuration
  - no need for a separate FA, all routers perform router advertisement which can be used instead of the special agent advertisement
  - MN can signal a sender directly the COA, sending via HA not needed in this case (automatic path optimization)
  - „soft“ hand-over, i.e. without packet loss, between two subnets is supported
    - MN sends the new COA to its old router
    - the old router encapsulates all incoming packets for the MN and forwards them to the new COA
    - authentication is always granted
- Mobile IP with reverse tunneling
  - Router accept often only “topologically correct” addresses (firewall!)
    - a packet from the MN encapsulated by the FA is now topologically correct
    - furthermore multicast and TTL problems solved (TTL in the home network correct, but MN is too far away from the receiver)
  - Reverse tunneling does not solve
    - problems with firewalls, the reverse tunnel can be abused to circumvent security mechanisms (tunnel hijacking)
    - optimization of data paths, i.e. packets will be forwarded through the tunnel via the HA to a sender (double triangular routing)
  - Reverse tunneling is backwards compatible
    - the extensions can be implemented easily and cooperate with current implementations without these extensions

Problems with mobile IP

- Security
  - authentication with FA problematic, for the FA typically belongs to another organization
  - no protocol for key management and key distribution has been standardized in the Internet
  - patent and export restrictions
- Firewalls
  - typically mobile IP cannot be used together with firewalls, special set-ups are needed (such as reverse tunneling)
- QoS
  - many new reservations in case of RSVP
  - tunneling makes it hard to give a flow of packets a special treatment needed for the QoS
- Security, firewalls, QoS etc. are topics of current research and discussions!
IP Micro-mobility support

- Micro-mobility support:
  - Efficient local handover inside a foreign domain without involving a home agent
  - Reduces control traffic on backbone
  - Especially needed in case of route optimization

- Example approaches:
  - Cellular IP
  - HAWAII
  - Hierarchical Mobile IP (HMIP)

- Important criteria:
  Security, Efficiency, Scalability, Transparency, Manageability

Cellular IP

- Operation:
  - “CIP Nodes” maintain routing entries (soft state) for MNs
  - Multiple entries possible
  - Routing entries updated based on packets sent by MN

- CIP Gateway:
  - Mobile IP tunnel endpoint
  - Initial registration processing

- Security provisions:
  - All CIP Nodes share “network key”
  - MN key: MD5(net key, IP addr)
  - MN gets key upon registration

Cellular IP: Security

- Advantages:
  - Initial registration involves authentication of MNs and is processed centrally by CIP Gateway
  - All control messages by MNs are authenticated
  - Replay-protection (using timestamps)

- Potential problems:
  - MNs can directly influence routing entries
  - Network key known to many entities (increases risk of compromise)
  - No re-keying mechanisms for network key
  - No choice of algorithm (always MD5, prefix+suffix mode)
  - Proprietary mechanisms (not, e.g., IPSec AH)

Cellular IP: Other issues

- Advantages:
  - Simple and elegant architecture
  - Mostly self-configuring (little management needed)
  - Integration with firewalls / private address support possible

- Potential problems:
  - Not transparent to MNs (additional control messages)
  - Public-key encryption of MN keys may be a problem for resource-constrained MNs
  - Multiple-path forwarding may cause inefficient use of available bandwidth
HAWAII

- Operation:
  - MN obtains co-located COA and registers with HA.
  - Handover: MN keeps COA, new BS answers Reg. Request and updates routers.
  - MN views BS as foreign agent.

- Security provisions:
  - MN-FA authentication mandatory
  - Challenge/Response Extensions mandatory

HAWAII: Security

- Advantages:
  - Mutual authentication and C/R extensions mandatory
  - Only infrastructure components can influence routing entries

- Potential problems:
  - Co-located COA raises DHCP security issues (DHCP has no strong authentication)
  - Decentralized security-critical functionality (Mobile IP registration processing during handover) in base stations
  - Authentication of HAWAII protocol messages unspecified (potential attackers: stationary nodes in foreign network)
  - MN authentication requires PKI or AAA infrastructure

HAWAII: Other issues

- Advantages:
  - Mostly transparent to MNs (MN sends/receives standard Mobile IP messages)
  - Explicit support for dynamically assigned home addresses

- Potential problems:
  - Mixture of co-located COA and FA concepts may not be supported by some MN implementations
  - No private address support possible because of co-located COA

Hierarchical Mobile IPv6 (HMIPv6)

- Operation:
  - Network contains mobility anchor point (MAP)
    - mapping of regional COA (RCOA) to link COA (LCOA)
  - Upon handover, MN informs MAP only
    - gets new LCOA, keeps RCOA
  - HA is only contacted if MAP changes

- Security provisions:
  - no HMIP-specific security provisions
  - binding updates should be authenticated
Hierarchical Mobile IP: Security

- Advantages:
  - Local COAs can be hidden, which provides some location privacy
  - Direct routing between CNs sharing the same link is possible (but might be dangerous)

- Potential problems:
  - Decentralized security-critical functionality (handover processing) in mobility anchor points
  - MNs can (must!) directly influence routing entries via binding updates (authentication necessary)

Hierarchical Mobile IP: Other issues

- Advantages:
  - Handover requires minimum number of overall changes to routing tables
  - Integration with firewalls / private address support possible

- Potential problems:
  - Not transparent to MNs
  - Handover efficiency in wireless mobile scenarios:
    - Complex MN operations
    - All routing reconfiguration messages sent over wireless link

DHCP: Dynamic Host Configuration Protocol

- Application
  - Simplification of installation and maintenance of networked computers
  - Supplies systems with all necessary information, such as IP address, DNS server address, domain name, subnet mask, default router etc.
  - Enables automatic integration of systems into an Intranet or the Internet, can be used to acquire a COA for Mobile IP

- Client/Server-Model
  - The client sends via a MAC broadcast a request to the DHCP server (might be via a DHCP relay)

DHCP - protocol mechanisms

- Server (not selected)
  - Determination of the configuration
- Client
  - Initialisation
  - DHCPDISCOVER reception
  - DHCPREQUEST (options) sent
  - DHCPACK received
  - Configuration completed
  - Dhcprelease
- Server (selected)
  - Determination of the configuration
- Dhcpoffer
  - Selection of replies
  - Dhcppacket
  - Confirmation of configuration
DHCP characteristics

- Server
  - several servers can be configured for DHCP, coordination not yet standardized (i.e., manual configuration)
- Renewal of configurations
  - IP addresses have to be requested periodically, simplified protocol
- Options
  - available for routers, subnet mask, NTP (network time protocol) timeserver, SLP (service location protocol) directory, DNS (domain name system)
- Security problems
  - no authentication of DHCP information specified

TCP Overview

- Transport control protocols typically designed for
  - Fixed end-systems in wired networks
- Research activities
  - Performance
  - Congestion control
  - Efficient retransmissions
- TCP congestion control
  - packet loss in fixed networks typically due to (temporary) overload situations
  - router have to discard packets as soon as the buffers are full
  - TCP recognizes congestion only indirectly via missing acknowledgements, retransmissions unwise, they would only contribute to the congestion and make it even worse

TCP slow-start

- sender calculates a congestion window for a receiver
- start with a congestion window size equal to one segment
- exponential increase* of the congestion window up to the congestion threshold, then linear increase
- missing acknowledgement causes the reduction of the congestion threshold to one half of the current congestion window
- congestion window starts again with one segment

*slow-start vs. exponential increase: window is increased by one for each acknowledgement, that is, 1 ! 2 ! 4 ! 8 … In other words, the slow-start mechanism is rather a "quick-start".

TCP fast retransmit/fast recovery

- TCP sends an acknowledgement only after receiving a packet
- If a sender receives several acknowledgements for the same packet, this is due to a gap in received packets at the receiver
- Sender can retransmit missing packets (fast retransmit)
- Also, the receiver got all packets up to the gap and is actually receiving packets
- Therefore, packet loss is not due to congestion, continue with current congestion window (fast recovery)
- In the following simplified analysis, we do consider neither fast retransmit nor fast recovery.
### TCP on lossy (wireless) link

- Without fast retransmit/fast recovery

#### Simple analysis model for lossy TCP

- Segment loss probability \( q = 1 - p \)
- We are interested in the throughput \( T \)

- If there are no losses (and all ACKs are received in time):
  - Number of segments \( S \) first doubles up to threshold \( W \) (slow start phase)
  - Number of segments \( S \) is incremented after \( S \) successful ACKs
  - At some point we reach the bandwidth of the channel \( B \)
- If there is a loss
  - We go back to \( S = 1 \)

#### Simple analysis of lossy TCP

- For not too high error probability \( q \) we are usually in the congestion mode (that is: not the slow start mode).
- The expected number of successful transmissions before we get an error is
  \[
  E = \sum_{i=0}^{\infty} i \cdot p^i (1 - p) = \frac{p}{1 - p}
  \]
- In the equilibrium, we are in the states 1, 2, 3, ..., \( S-1, S \), and then back to 1 because we have a missing ACK, that is, we have \( 1 + 2 + \ldots + S \frac{1}{2} S^2 / 2 \) successful transmissions.
- With \( S^2 / 2 = E = p / q \) we get \( T = S / 2 = \sqrt{1 / 2} \cdot p / q = \Theta(1 / \sqrt{q}) \), for \( p = \Theta(1) \)

#### Lossy TCP: Graphical Interpretation

- Plot of \( T(p) \), with \( B = 50 \)
- Note that 1% faulty transmissions is enough to degrade the throughput to about 14% of the bandwidth
- 10% error rate gives about 4% of possible bandwidth.
- The higher the bandwidth, the worse the relative loss.
Mobility and TCP

- TCP assumes congestion if packets are dropped
  - typically wrong in wireless networks, here we often have packet loss due to transmission errors
  - furthermore, mobility itself can cause packet loss, if e.g. a mobile node roams from one access point (e.g. foreign agent in Mobile IP) to another while there are still packets in transit to the wrong access point and forwarding is not possible

- The performance of an unchanged TCP degrades severely
  - however, TCP cannot be changed fundamentally due to the large base of installation in the fixed network, TCP for mobility has to remain compatible
  - the basic TCP mechanisms keep the whole Internet together

Early Approach: Indirect TCP (I-TCP)

- segments the connection
  - no changes to the TCP protocol for hosts connected to the wired Internet, millions of computers use (variants of) this protocol
  - optimized TCP protocol for mobile hosts
  - splitting of the TCP connection at, e.g., the foreign agent into two TCP connections, no real end-to-end connection any longer
  - hosts in the fixed part of the net do not notice the characteristics of the wireless part

I-TCP socket and state migration

Indirect TCP Advantages and Disadvantages

+ no changes in the fixed network necessary, no changes for the hosts (TCP protocol) necessary, all current optimizations to TCP still work
+ transmission errors on the wireless link do not propagate into the fixed network
+ simple to control, mobile TCP is used only for one hop, between a foreign agent and a mobile host
+ therefore, a very fast retransmission of packets is possible, the short delay on the mobile hop is known
  - loss of end-to-end semantics, an acknowledgement to a sender does now not any longer mean that a receiver really got a packet, foreign agents might crash
  - higher latency possible due to buffering of data with the foreign agent and forwarding to a new foreign agent
  - high trust at foreign agent; end-to-end encryption impossible
Early Approach: Snooping TCP

- Transparent extension of TCP within the foreign agent
  - buffering of packets sent to the mobile host
  - lost packets on the wireless link (both directions!) will be retransmitted immediately by the mobile host or foreign agent, respectively (so called “local” retransmission)
  - the foreign agent therefore “snoops” the packet flow and recognizes acknowledgements in both directions, it also filters ACKs
  - changes of TCP only within the foreign agent

Snooping TCP

- Data transfer to the mobile host
  - FA buffers data until it receives ACK of the MH, FA detects packet loss via duplicated ACKs or time-out
  - fast retransmission possible, transparent for the fixed network
- Data transfer from the mobile host
  - FA detects packet loss on the wireless link via sequence numbers, FA answers directly with a NACK to the MH
  - MH can now retransmit data with only a very short delay
- Integration of the MAC layer
  - MAC layer often has similar mechanisms to those of TCP
  - thus, the MAC layer can already detect duplicated packets due to retransmissions and discard them
- Problems
  - snooping TCP does not isolate the wireless link as good as I-TCP
  - snooping might be useless depending on encryption schemes

Fast retransmit/fast recovery

- Problem: Change of foreign agent often results in packet loss
  - TCP reacts with slow-start although there is no congestion
- Solution: Forced fast retransmit
  - as soon as the mobile host has registered with a new foreign agent, the MH sends (three) duplicated acknowledgements on purpose
  - this forces the fast retransmit mode at the communication partners
  - additionally, the TCP on the MH is forced to continue sending with the actual window size and not to go into slow-start after registration
- simple changes result in significant higher performance
- what a hack…

Early Approach: Mobile TCP

- Special handling of lengthy and/or frequent disconnections
- M-TCP splits as I-TCP does
  - unmodified TCP fixed network to supervisory host (SH)
  - optimized TCP SH to MH
- Supervisory host
  - no caching, no retransmission
  - monitors all packets, if disconnection detected
    - set sender window size to 0
    - sender automatically goes into persistent mode
  - old or new SH re-open the window
- maintains end-to-end semantics, supports disconnection, no buffer forwarding
- does not solve problem of bad wireless link, only disconnections
- adapted TCP on wireless link; new software needed
Transmission/time-out freezing

- Mobile hosts can be disconnected for a longer time
  - no packet exchange possible, e.g., in a tunnel, disconnection due to overloaded cells or multiplex with higher priority traffic
  - TCP disconnects after time-out completely

- TCP freezing
  - MAC layer is often able to detect interruption in advance
  - MAC can inform TCP layer of upcoming loss of connection
  - TCP stops sending, but does now not assume a congested link
  - MAC layer signals again if reconnected

  + scheme is independent of data
  - TCP on mobile host has to be changed, mechanism depends on MAC layer

Selective retransmission

- TCP acknowledgements are often cumulative
  - $\text{ACK} n$ acknowledges correct and in-sequence receipt of packets up to $n$
  - if single packets are missing quite often a whole packet sequence beginning at the gap has to be retransmitted (go-back-$n$), thus wasting bandwidth, especially if the bandwidth-delay product is high.

- Selective retransmission as one solution
  - RFC2018 allows for acknowledgements of single packets, not only acknowledgements of in-sequence packet streams without gaps
  - sender can now retransmit only the missing packets

  + much higher efficiency
  - more complex software in a receiver, more buffer needed at the receiver

Transaction oriented TCP

- TCP phases
  - connection setup, data transmission, connection release
  - using 3-way-handshake needs 3 packets for setup and release, respectively
  - thus, even short messages need a minimum of 7 packets!

- Transaction oriented TCP
  - RFC1644, T-TCP, describes a TCP version to avoid this overhead
  - connection setup, data transfer and connection release can be combined
  - thus, only 2 or 3 packets are needed

  + Efficiency
  - Requires changed TCP

Comparison of different approaches for a “mobile” TCP

(Schiller)
Recent work

- Initial research work
  - Indirect TCP, Snoop TCP, M-TCP, T/TCP, SACK, Transmission/time-out freezing, …
- TCP over 2.5/3G wireless networks
  - Fine tuning today’s TCP
  - Learn to live with
    - Data rates: 64 kbit/s up, 115-384 kbit/s down; asymmetry: 3-6, but also up to 1000 (broadcast systems), periodic allocation/release of channels
    - High latency, high jitter, packet loss
  - Suggestions
    - Large (initial) sending windows, large maximum transfer unit, selective acknowledgement, explicit congestion notification, time stamp, no header compression
  - Already in use
    - i-mode running over FOMA
    - WAP 2.0 (“TCP with wireless profile”)

\[ BW \leq \frac{0.93 \cdot MSS}{RTT \cdot \sqrt{p}} \]

- max. TCP BandWidth
- Max. Segment Size
- Round Trip Time
- loss probability

Recent work

- Performance enhancing proxies (PEP, RFC 3135)
  - Transport layer
    - Local retransmissions and acknowledgements
  - Additionally on the application layer
    - Content filtering, compression, picture downscaling
    - E.g., Internet/WAP gateways
    - Web service gateways?
  - Big problem: breaks end-to-end semantics
    - Disables use of IP security
    - Choose between PEP and security!
- More open issues
  - RFC 3150 (slow links)
    - Recommends header compression, no timestamp
  - RFC 3155 (links with errors)
    - States that explicit congestion notification cannot be used
    - In contrast to 2.5G/3G recommendations!
